

An Introduction to SAN and Fixed Block Disk for ECKD Users

Samuel D. Cohen IBM zSystems Consultant Levi, Ray & Shoup, Inc <u>sam.cohen@lrs.com</u> (217) 862-9227

Overview

- z/OS uses primarily Variable-Block disk storage (aka Enhanced Count-Key-Data (ECKD)), while other IBM zSystem operating systems can use ECKD and/or 512-byte Fixed Block (FB) disk.
- Accessing FB disk uses Fibre Channel instead of FICON
 - Same hardware
 - Different communication protocols
- This presentation will compare/contrast accessing ECKD disk vs. FB disk
 - Part 1 Hardware and Terminology
 - Part 2 Example from a real system

Background: IOCDS

- The I/O Configuration Dataset (IOCDS) defines connections between the zSystem server and attached peripheral devices
- I/O Path Management is performed by the I/O Subsystem
 - Separate from the processor(s) used by the operating system
- Primary Entries in IOCDS
 - RESOURCE (LPAR Definitions and associated LPAR IDs (0-F))
 - CHPID (logical and physical ID and associated protocol)
 - Physical connection depends on the hardware location in the I/O cages and is identified via a Physical Channel Path ID (PCHID).
 - Up to 256 subchannels on a CHPID (aka channel), depending on attached device
 - CNTLUNIT (control unit to receive I/O for routing to device)
 - Connected to one or more CHPID(s)
 - May have multiple control units on one CHPID via CUADDR parameter
 - IOADDR (individual peripheral devices)
 - Connected to a one or more CNTLUNITs

Background: Peripheral Devices

- Traditionally, peripheral devices are connected to a control unit, and control units have "channel" connections to the zSystems server
- Control Units can be directly connected to the server or go through a switch (also called a "director"). Control Units can also be daisy-chained on a single path (physically or logically, depending on the device)
- Addressing peripheral devices is based on a 4-digit (hex) I/O address. It used to be a concatenation of "channel" address with "unit" address, although that relationship went away in the 1990s. You may hear the term "cuu", "ccuu" or "UCB".

Background: Peripheral Devices

Example of a Disk Subsystem with 1024 addressable devices:

- 4 Channels connected between server and tape subsystem
- 4 Control Units

256 disk devices defined per Control Unit (architectural limit)

The Control Units share the 4 channels by having unique Control Unit addresses within the subsystem. These address match the CUADDR parameter on each CNTLUNIT statement in the IOCDS Different peripherals have different architectural limits

Background: FICON

- Fiber Channel Connection (FICON) attachment uses fiber for communication between the IBM zSystem and the peripheral control unit
 - The IOCDS defines which FICON ports are used by a Control Unit, and which devices are attached to a particular Control Unit
 - Path management is determined by the I/O subsystem
 - Outbound communication is independent from inbound communication
 - Operating Systems (z/OS, z/VSE, z/VM, z/TPF, Linux) are not involved in path selection; they send the message to the I/O subsystem for handling

Background: FCP

- Fibre Channel Protocol (FCP) attachment is handled differently from FICON attachment, although the hardware is the same
 - FCP port is assigned a World-Wide Port Name (WWPN)
 - One WWPN per port
 - An FC Port is to a WWPN as an OSA Port is to a MACADDR
 - IBM zSystems define WWPNs based on CPU Serial number and PCHID
 - Multiple subchannels available but every subchannel sees the same traffic because traffic is routed between WWPNs on both sides of the connection
 - No path management by I/O subsystem
 - Path management by the operating system(s)

Background: NPIV

- How do you keep traffic different FCP subchannels from seeing traffic on all other subchannels?
- Virtualization!!
- N_Port ID Virtualization (NPIV) creates a virtual WWPN for each channel
 - Limited to 64 subchannels per FCP port in current hardware models
- Using NPIV, traffic between an FCP subchannel and a disk subsystem will not be seen by any other FCP subchannel
 - Traffic could be seen at the disk subsystem channel interface unless it also uses NPIV

 $\ensuremath{\mathbb{C}}$ 2023, Levi, Ray & Shoup, Inc.

Background: SAN "Fabric"

- IBM zSystems cannot directly connect to FC HBAs
 - Must use a SAN switch that is certified for use with IBM zSystems
- SAN provides the path management between FC-attached devices
- "Zoning" is the process of pairing these FC attachments
 - WWPNs are used in the zoning process
 - Not limited to a single point-to-point definition at each end
 - Can have 1:1, 1:many, many:1 or many:many
 - Pathing is managed by a multipath background process/started task/daemon in the host operating system
 - Configured by querying the SAN and devices attached at other end of the zone
- Usually want 2 separate fabrics for redundancy

ECKD Storage Devices

- 1 or more Hardware Bus Adapters (e.g. FICON channel)
- Pre-defined Logical Control Units or Logical Subsystems (LSS number = CUADDR on IOCDS CNTLUNIT statement)
- Pre-defined Unit Addresses (0-255 per LCU)
 - Size of each logical disk is pre-defined
- IOCDS should have configuration statements matching pre-defined definitions in disk subsystem
 - IOCDS doesn't care about "base" vs. "alias" devices, HCD does
 - For z/VM to see alias disk devices when running alongside z/OS, ensure that the alias devices in HCD are in channel subsystem 0 (z/OS default is channel subsystem 1)

FB Storage Devices

- 1 or more Hardware Bus Adapters (e.g. FC channel)
- Pre-defined 16-digit Host Addresses (WWPNs)
- No Logical Control Units
- Pre-defined Logical Units (LUNs)
 Size of each LUN is pre-defined
- SAN Zones providing the linkage between IBM zSystems and the disk Host Bus Adapters (HBAs; e.g. channels)
- Disk subsystem definitions for the IBM zSystems WWPNs that will be accepted and matched with local LUNs

SAN Zoning

- Independent of both server and storage
- Provides pathing for I/O
- Must be configured and activated before use
 - Many fabric administrators expect to see WWPNs before they are in use by the server...this is not necessarily true for IBM zSystems
 - Connectivity issues are usually due to misconfiguration
- Zoning involves WWPNs only
 - LUNs are managed at the disk subsystem
- Disk subsystem may require pre-definition of incoming WWPNs in addition to SAN zoning

Steps in SAN Zoning

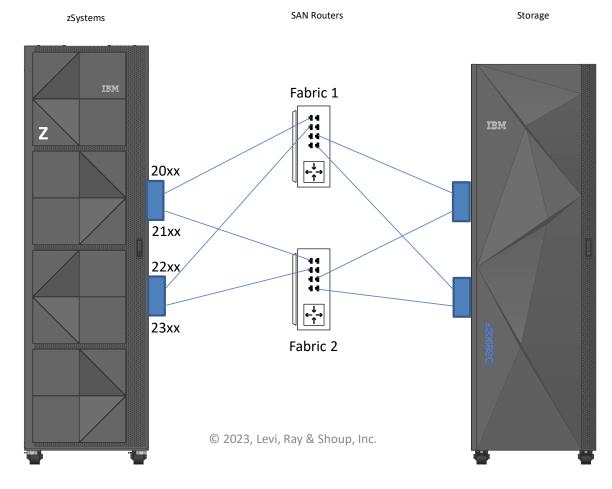

- Identify the WWPNs you want to connect from both ends of the connection
- Define an alias for the WWPNs at each side of the connection
 - Suggestion: If using NPIV, put all the virtual WWPNs for one subchannel (across all LPARs) in the same alias
- Create a zone containing the aliases for each side of the connection
- Add the new zone to the zone configuration
- Activate the zone configuration

Lost Yet? Let's take a break....

• IOCDS source for an FCP channel

Boot program selector	0		
Boot record logical block address	00000000000C8		
Operating system specific load param	eters cons=SYSG		

z/VM Use of FB Disks

- Emulated FBA (EFBA)
 - Define a "dummy" FBA address linked to an FCP channel+WWPN+LUN
 - Can define multiple FCP channel+WWPN+LUN combinations
 - z/VM then does multitasking, but only if initial channel is busy

Example:

SET EDEVICE 3000 TYPE FBA ATTR FLASH,

FCP_DEVICE 2101 WWPN 0123456789ABCDF0, FCP_DEVICE 2201 WWPN 0123456789ABCDEF, FCP_DEVICE 2301 WWPN 0123456789ABCDF0

z/VM: LGR Support

- If you will be attaching FCP subchannels to a guest that could be relocated to another z/VM system, define EQIDs for each subchannel and use them for attaching FCP to the guest:
- Assuming 4 FCP channels start at 2000, 2100, 2200 and 2300:
 - In SYSTEM CONFIG:

Rdevice 2000	EQID FCP00 Type FCP
Rdevice 2100	EQID FCP00 Type FCP
Rdevice 2200	EQID FCP00 Type FCP
Rdevice 2300	EQID FCP00 Type FCP

– In VM Directory for a guest:

COMMAND ATTACH EQID FCP00 TO * AS 2000 COMMAND ATTACH EQID FCP00 TO * AS 2100 COMMAND ATTACH EQID FCP00 TO * AS 2200 COMMAND ATTACH EQID FCP00 TO * AS 2300

z/VSE Use of FB Disks

• Assume DOSRES is at address A00, SYSWK1 is at address A01

ADD A00:A01,FBA ADD 2000 AS 200,FCP ADD 2100 AS 210,FCP DEF SCSI,FBA=A00,FCP=200,WWPN=0123456789ABCDEF,LUN=0000 DEF SCSI,FBA=A01,FCP=200,WWPN=0123456789ABCDEF,LUN=0001

- Additional path only used if prior path is busy
- If using direct SCSI connection to disk, LUN can be up to 28G
- If using z/VM EFBA, disk is defined as 9930-20 and limited to 2G

Linux use of FB disks

- Enable Multipath Daemon and FCP Devices
 - SLES:
 - Use YaST to configure devices during initial installation
 - RedHat:
 - Run /sbin/mpathconf to create multipath config, then enable multipathd
 - Define FCP device addresses, WWPNs and LUNs in /etc/zfcp.conf
 - May need to run cio_ignore –r FCP_addresses to let FCP channels come online
- Multipath Daemon may use round-robin for I/O distribution, but depends on multipath.conf settings

- Defaults are usually sufficient
